GLOSSARY

Glossary

DAPI 4',6-diamidino-2-phenylindole; a fluorescent stain that binds strongly to DNA and serves to mark the nucleus in fluorescence microscopy

DEPC diethyl-pyro-carbonate; used to remove RNA-degrading enzymes (RNAases) from water and laboratory utensils

DMSO dimethyl sulfoxide; organic solvent, readily passes through skin, cryoprotectant in cell culture

EDTA Ethylene-diamine-tetraacetic acid; a chelating (two-pronged) molecule used to sequester most divalent (or trivalent) metal ions, such as calcium (Ca^{2+}) and magnesium (Mg^{2+}), copper (Cu^{2+}), or iron (Fe^{2+} / Fe^{3+})

Introduction

1.1 Electric Vehicles

There are many motivating factors behind the development of electric cars. These vehicles utilize new technologies and represent humanity moving forward in both imagination and respect for the environment.

1.1.1 Pollution

Electric vehicles are advantageous over traditional ICE vehicles as they operate with zero emissions. These vehicles have no exhaust, so therefore have no emissions. While this does not make them completely pollutant free, it does help limit and control the emissions being produced by the act of transport. It is important to remember when discussing electric vehicles that the components must be manufactured using industrial processes and the act of generating electricity. This does not make them truly carbon neutral, but helps limit the sources of pollution. It is much more easier to manage the pollution produced from one power plant, than that from thousands upon millions of vehicles.

Insulin stimulates the following processes:

- muscle and fat cells remove glucose from the blood,
- cells breakdown glucose via glycolysis and the citrate cycle, storing its energy in the form of ATP,
- liver and muscle store glucose as glycogen as a short-term energy reserve,

2

Aims of the project

2.1 Final Aim

The Ultimate goal of the project is to investigate the viability of distrubted systems in a automotive environment. This will culminate into a completed system, provided data logging functionality and a user interface to view the live data.

2.2 Preliminary aims

Preliminary aims of the project are to.

1. Investigate messaging protocols inside a minimal embedded systems
2. Develop GPS capability
3. Develop BMS capabilty
4. Integrate this data into a user display
5. Log this data to be reviewed later

System Design

4.1 GPS

4.1.1 Hardware

A vital part of the data logging and user-interface of the software is finding the cars current location. This is done by the use of a off-the self GPS unit. Currently the system is using a Qstar MODEL NEEDED [CITATION NEEDED] usb equipped GPS receiver. This receiver operates at a rate of 10hz [CITATION NEEDED], though it can be set to operate at a slower frequency of 1hz. For the purposes of recording positional data, along with estimating the vehicles current speed, the unit should run as fast as possible. The extra precision is useful for the data-logging aspect, with no negative effects on the user-display aspect.

The GPS device can be enumerated as a standard serial port. This is beneficial as it can be used on any device that has the correct drivers and a available usb port. As it appears as a normal serial port, it can be queried using standard system routines. This allows the program that reads the device to operate any custom knowledge of the device it is connected to, aside from the serial parameters to make the connection.

4.1.2 Drivers

While the Eyebot M6 has hardware usb support, it was not immediately compatible with the GPS sensor. Various versions of usb-serial drivers where tried (see figure X.X) each with their own problems. The main cause of this difficulty was the out-dated Linux kernel being run in the system. This was kernel version number 2.6.17 and was

4. SYSTEM DESIGN

released in 2006, which is 5 years old as of writing [OSNEWS citation]. This was a major cause of incompatibilities, as the GPS receiver was manufactured a significant time after this kernel was written. The drivers had no clue as to what the usb product keys were, nor the specific quirks that the devices may have had.

The first driver attempted was the generic usb-serial driver, included as a kernel module in 2.6.17. This drivers success would mean that the sensor and program could be easily installed in just about any machine running Linux. The driver would have matured after the 2.6.17 kernel, and newer kernels would have support by default. This is beneficial to the system as it would require the least amount of configuration and setup if the GPS program was set to run in a different machine.

Sadly this driver did not perform correctly with the GPS device. While the driver was able to be loaded into the kernel without any errors, it caused problems when trying to associate with the GPS. The device appeared to use bulk endpoints [CITE/EXPLAIN], which were unsupported by the generic driver. This caused strange symptoms in the operating system. The main symptom of an incorrect driver was the generation of the `/dev/ttyUSB0` device. This availability of this device implies that a `tty` is available to read/write from. Due to the incompatibility of the driver, this serial port would never report any bytes to be read, which is why it is unsuitable for use with this device. Customizing the generic driver to support this device would be unfeasible because it is unlikely that newer versions of this driver would support the device. This leads to the situation that if the GPS program is ported to a different machine, a custom version of the generic usb serial drivers would have to be ported as well.

As the GPS device did not work with the generic serial drivers, alternative drivers were investigated in order to support this device. Experiments indicated that this device was automatically detected and loaded in a newer kernel. This was kernel 2.X.X running on a x86 Intel machine. This functioned correctly and was able to communicate with the GPS device at the full rate of 10hz. The driver used by this kernel was called `cdc-acm`. Further investigation showed that this driver could be included as a kernel module for the gumstix platform.

This driver was not immediately compatible with the device. This was because the device was manufactured after the kernel [CITE ME]. As such the driver did not recognize the manufacturer ID and product ID of the GPS[see figure X.X]. The driver was then modified to include this information and re-deployed to the eye-bot. This was

successful in creating the virtual serial device inside `/dev`, and also in allowing data to be read from this device.

While the `cdc-acm` driver was able to be loaded and functioned, it still contained errors. If the system was under intense CPU load, the program may not run quick enough to remove all the data from the serial port buffer.[CITE TTY/SERIAL BUFFERS]. This would cause the operating system to throttle the port. Examination of the driver source code reveals that new information is dropped while this driver is throttled[`cdc-acm/2.6.17-arm`]. This is acceptable behaviour in this instance, however this driver had a race condition. If the TTY was throttled under certain conditions, it would be unable to un-throttle later on. This cause the TTY to drain its buffer and never accept any new data from the GPS even if its buffer was empty. [SOURCE CODE ANALYSIS SECTION HERE]. The driver was further modified to include spin-locks, a primitive kernel locking technique, in order to prevent this situation. The driver is now able to run for extended periods of time without locking up, enabling a reliable GPS reporting mechanism to be developed.

4.1.3 Design

Development of the GPS reporting component was done in C. This was chosen as it is a relatively low level language, with wide support. It is simpler to understand than more complicated object oriented style languages. This makes it a good choice for the GPS reporting mechanism, as it only has to do one task. In order to ensure that the code can be easily modified by future programmers, the structure of this program is simple. It runs in only one-thread, aside from the back ground ZeroMQ threads, and thus requires no concurrency management.

This first iteration of this code used blocking ports and read a single byte at a time. This was the style used to match existing examples [CITE PREVIOUS THESIS]. This was a functional design however it did lead to some problems. One problem with this approach was excessive throttling. The process would be woken up every time one character could be read, and would only remove one character from the buffer, even if there were hundreds waiting. This is a bad situation, as the process will continually be awoken to do trivial work. This steals cpu-time from another process, and caused the program to appear sluggish. This design was also in-sufficient as blocked the process while attempting to read from the port. This would cause the program to appear to

4. SYSTEM DESIGN

hang if no data was available. It made it difficult to diagnose errors with this program. Figure X.X shows the process logic of the first iteration of the GPS controller.

The design was refined in order to support bulk-reads and non-blocking operation. This fixes the two problems with the first approach. Rather than reading one character at a time, the program now reads as many as possible and stores the information into its own circular buffer. This allows the serial port to be purged as quickly as possible. It also has the added feature of allowing the program to decide how to discard messages in the case that it cannot keep up with the GPS.

Table X.X shows the protocol for the GPS message when transmitted over the network. The protocol uses a binary format instead of an ASCII based one. This reduces the space/data transmitted over the link, which helps reduce cost and improve speed. The motivation for ASCII based protocols is that control characters can be used to help synchronize the data. As this design uses ZeroMQ in order to manage the flow of data, such control characters are unnecessary. All values are transmitter in network order, this is big-endian order so that the most significant byte is transmitted first.
